

## REMARKS/ARGUMENTS

Claims 1-24 are pending. Claims 1-18 have been canceled. Claims 19-24 have been rejected. Claims 25-32 have been added. Applicants hereby elected to prosecute the Claims of Group III (Claims 19-24) without traverse.

The amendment of Claim 19 is supported by original Claim 1. The amendment of Claim 20 is supported by original Claim 1. Support for new claims 25-32 are supported individually and in order by original claims 7-10, 12 and 3-5.

### THE §112(a) REJECTION

Claim 20 has been rejected under 35 U.S.C. §112 second paragraph as being indefinite.

Claim 20 was rejected, because it was “confusing . . . because it is unclear whether the filaments have a sheath-core structure or the reinforcing fiber has a sheath core structure.” Claim 20 has been amended making it clear that it is the filaments that have the sheath-core structure. For this reason, Claim 20 is definite and applicants respectfully request withdrawal of this rejection.

### THE §103(a) REJECTION

#### *Rejection of Claim 19:*

Claims 19, 23 and 24 have been rejected under 35 U.S.C. 103(a) as being unpatentable over U.S. Patent No. 4,414,030 to Restrepo (herein, Restrepo) in view of Japanese Patent Publication No. 06-122821A to Martinus et al., (herein, Martinus) and U. S. Patent No. 4,552,805, to Fish Jr, et al., (herein Fish). Applicants traverse the rejection and respond as follows.

The Office Action asserts that Restrepo describes that the “mixing operation causes the fibrils of the fibrous material to become further fibrillated or refibrillated.” Applicants do not disagree, but point out that Restrepo when mixing with concrete and water specifically teaches that “besides breaking the plastic ribbon

apart into separate monofilaments, secondary branched microfibrils or fibrets are brought forth . . . at points along the sides of the monofilament's length." (col. 5, lines 57-60). Thus, it is clear that the simple batch mixing of concrete and water in a conical mixer with the fiber ribbons of Restrepo completely fibrillates into individual filaments and starts to micro-fibrillate these filaments all along their length. (col. 5, lines 45-50).

The Office Action asserts that one of ordinary skilled in the art would modify the process of Restrepo by using the method of Martinus so as to form frayed fibers at the end of the fibers. The Office Action, however, states that "the mixer transmits higher shearing force to the mixture to thereby form two or more fibrils on the ends of the fibers." The Office Action further states that "it would have been prima facie obvious to one ordinary skill in the art . . . and one of ordinary skill in the art would have been motivated to significantly fibrillate the ends of the reinforcing fibers during the mixing operation in the process of Restrepo as taught by Martinus." Finally, the Office Action stipulated that "the majority (e.g., at least 50%) of the fibers in the modified process of Restrepo in view of Martinus et al. would have been fibrillated at their end."

Applicants disagree and respond as follows. Restrepo clearly teaches that simple mixing of concrete, water and plastic ribbon (i.e., low shear propeller conical mixer) completely fibrillates the starting plastic ribbon into filaments which then are further fibrillated all along their lengths in a time that is on the order of 6 minutes or less. (col. 7, lines 40-42) and that this is desirable for concrete. In contrast, Martinus specifically describes high shear mixing, where the mixer has to be cooled (paragraph 8 of machine translation). Further, Martinus specifically cites EP261820 (attached) as having similar compositions as that of Martinus. In EP261820, it is apparent that the filler described by Martinus involves fillers (e.g., zinc oxide) having very small particle size (0.1 to 20 micrometers) to make paper products of some sort. (page 3, line 49).

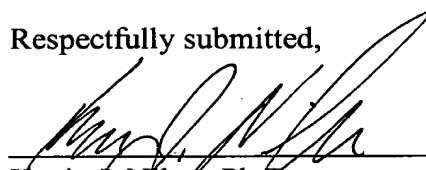

In contrast, the present invention of Claim 19 requires the mixing of concrete, water and fiber, the fiber being substantially only fibrillated at the ends by the mixing. Consequently, it would make no sense to one of ordinary skill in the art

to use the higher shearing method of Martinus to mix concrete having large aggregates (e.g., rocks and sand) to make fibers only frayed at the ends considering Restrepo clearly describes that simple mixing in a conical mixer completely fibrillates and starts to micro-fibrillate the fiber. That is, a method imparting higher shear energy to a concrete mixture (Martinus) compared to Restrepo, if anything, will be expected to not only completely fibrillate the fiber, but even further micro-fibrillate the filaments that are produced using the concrete mixing method of Restrepo.

From this, regardless of what Fish describes for fibrillating fibers and using such fibrillated fibers for use in *thermoplastic composites*, the combined method of Restrepo using the mixing method of Martinus would clearly fail to make the invention as required by Claim 19. That is, the method proposed would completely fibrillate fibers in a concrete mixture. Consequently, Claim 19 and Claims dependent therefrom are non-obvious and as such are patentable.

Considering the foregoing amendments and reasons, Claims 19-32 are definitive, non-obvious and patentable. Applicants, therefore, respectfully request withdrawal of all rejections and allowance of Claims 19-32.

Respectfully submitted,

Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

**Description**Field of the invention

- 5 The present invention relates, in general, to the manufacture of filled fibrous sheet materials and, in particular, to compositions containing a filler, to methods of manufacturing fibrous sheet materials, especially paper, board, and nonwovens, using such filler compositions, and to fibrous sheet materials manufactured by such methods.

10 Background to the invention

- It is common practice in making paper and board to add particulate materials, for example mineral pigments, for filling and loading purposes to the pulp slurry from which the paper or board is made. The common mineral fillers are considerably cheaper than pulp and therefore reduce the cost of the paper or board product; moreover, fillers may be used to improve such properties as the brightness, opacity, handle, ink receptivity and print clarity of the product. However, fillers almost invariably reduce the strength of the product.

- Furthermore, there is a tendency for filler particles to be lost into the water which drains from the fibrous web formed from the pulp slurry, although the amount of filler that is lost will depend upon many factors such as the particle size and the specific gravity of the filler.

- The loss of filler can be reduced by the addition of a retention aid. Certain retention aids act to neutralise the negative charges that develop on the surfaces of the filler particles and fibres and thereby to encourage co-flocculation of the filler and fibres, such charge-biasing retention aids including polymeric flocculating agents having a molecular weight of the order of  $10^3$  to  $10^5$  and which contain amine or quaternary ammonium groups, for example polyamide-epichlorohydrin condensates or poly(dimethyldiallylammonium chloride). More effective as retention aids, however, are polymeric flocculating agents having higher molecular weights, usually of the order of  $10^6$  to  $10^7$ , amongst which the ionic polymers, especially ionic copolymers, of acrylamide are commonly used, although polyethylene-imines and vinylpyridine polymers are also effective. The high molecular weight polymers may be referred to as "bridging" polymers, since they encourage flocculation by forming molecular bridges between particles to which they are adsorbed. The use of fillers and retention aids in papermaking is described, for example, in the articles entitled "Paper" and "Papermaking Additives" in the Kirk-Othmer Encyclopedia of Chemical Technology, third edition, volume 16, pages 768 to 825. Interesting flocculants, which may be used in papermaking, e.g. in the presence of cationic starch, were recently disclosed in EP-A-0,172,723. The teaching of these documents is incorporated herein by reference.

- U.S. Patent 2,027,090 (Carter) discloses a method of incorporating a substance into paper or the like by dispersing the substance in a continuous phase capable of coagulating to a firm gel, an aqueous solution of viscose cellulose being a particular example of such a phase. The gel is subdivided into particles (as in the papermaking beater). Furthermore, fibres are bound into the gel in such a manner as to protrude from the said gel particles; preferably such fibres are initially introduced into and dispersed throughout the liquid used to make the colloid dispersion which constitutes the said continuous phase. The gel particles are described and illustrated as enveloping, encysting or enclosing the particles of dispersed substance.

- Carter's method is suitable for incorporating into paper sticky or gummy substances such as a phenol-formaldehyde condensation product, although mineral fillers are mentioned in passing. The said fibres (which serve as "anchors" for the gel particles) are preferably the same as those of papermaking pulp stock, although rayon and asbestos fibres are also specifically mentioned.

- In order to achieve a high filler content whilst maintaining satisfactory strength properties, in particular tensile strength and burst strength, it has been proposed to employ a preflocculated filler composition, that is to say a suspension of filler to which a flocculating agent, in particular a highmolecular-weight synthetic polymer, is added before the filler is incorporated into the papermaking stock (see M.C.Riddell et al., Paper Technology, 17 (2), 76 (1976) and GB-A 1 552 243 the teaching in which is incorporated herein by reference).

- It has been found that the incorporation of filler into paper and other fibrous sheet products by conventional procedures gives rise to products having a poor tear strength, with difficulty in maintaining good formation and adequate tensile properties.

Summary of the invention

- 60 The present invention now provides a filler containing composition suitable for use in the manufacture of fibrous sheet materials, which composition comprises (a) filler particles, (b) synthetic organic fibres, and (c) a polymeric material that functions as a coupling agent between the filler particles and the said fibres (b).

- It is usually advantageous to employ preflocculated fillers in papermaking and the like systems. Accordingly, it is preferred that the present compositions contain (d) a flocculating agent for the filler parti-

cles and/or that they contain, as component (c), a polymer or combination of polymers that also functions as a flocculating agent for the filler particles. An adjuvant that enhances the efficacy of the flocculating agent and/or the coupling agent may also be included.

It has been found that the inclusion of the fibres (b) in a filler composition according to this invention can provide an improvement in the tear strength of fibrous sheet materials into which the filler is incorporated, even at high filler levels, whilst maintaining a satisfactory tensile strength. The fibres (b) have also been found, even at high filler contents, to maintain a surprisingly high bulk and porosity in the fibrous sheet material. It is envisaged that the invention will offer significant benefits in processes for the manufacture of wet-laid fibrous sheet products, especially by improving the drainage of water from the web during formation, thereby reducing the drying load, and by permitting increased refining, an increase in filler content or a decrease in grammage (basis weight or weight per unit area) whilst maintaining satisfactory strength properties, notably tear strength, in the finished sheet.

Thus, the present invention also provides a process for the manufacture of a fibrous sheet material, e.g. paper, by dewatering an aqueous slurry of fibres. Commonly by the draining of water therefrom), wherein a filler composition according to this invention is added to the slurry of fibres before the dewatering commences. In a continuous process, this means that the filler composition is added to the said slurry of fibres at a point upstream of the zone in which water is drained from the slurry to form the sheet (e.g. the zone defined by the forming section of a conventional machine for the production of paper, board or wet-laid non-wovens).

The filler composition will usually be added in the form of an aqueous composition, especially one containing preflocculated filler. Such an aqueous composition may be prepared from a dry or concentrated-liquid formulation containing two or more of the components (a) to (d) by mixing it with water and with the remainder, if any, of the said components.

The present invention also provides a fibrous sheet material that comprises a matrix of first fibres having distributed therein filler particles (preferably flocculated), second fibres that are fibres (b) as defined above and a polymeric material that functions as a coupling agent between the said filler particles and the fibres (b).

#### Brief Description of the Figures

Figure 1 is a photomicrograph of polyester fibres for use as component (b) before the addition of filler and coupling agent.

Figure 2 is a photomicrograph of polyester fibres of the type shown in Figure 1 to which calcium carbonate filler particles (flocculated with a polyacrylamide) have been coupled with a cationic starch.

Figure 3 is a photomicrograph of a fibre from a system similar to that of Figure 2.

Figure 4 is a photomicrograph of fibres from a system similar to that of Figure 2.

Figure 5 is a photomicrograph of a polyester fibre to which calcium carbonate filler particles are coupled with a modified guar gum, the latter also acting as a flocculant for the filler particles.

The magnification of Figures 3-5 is approx. 8.33 times that of Figures 1 and 2.

#### Description of preferred embodiments

In most cases, a mineral filler will be employed. Any of the conventional mineral fillers may be used, including clay (e.g. kaolin or china clay), titanium dioxide, barium sulfate, zinc sulfide, lithopone, satin white, talc, synthetic silicates (e.g. aluminium silicate), alumina, silica and calcium carbonate (e.g. precipitated calcium carbonate or ground calcium carbonate, such as chalk whiting). However, the synthetic polymeric fillers also come into consideration.

The filler particle size will usually be in the range from 0.1 to 20  $\mu\text{m}$ .

Non-fibrous fillers are, in general, preferred: upon flocculation, a fibrous filler could form knots, clumps or like blemishes that would spoil the formation of the sheet product.

The flocculation of the filler particles may, for example, be effected by using as component (d) any of the flocculating agents, especially the water-soluble synthetic polymers, that could be used conventionally as retention aids in papermaking. It is preferred to use as component (d) a flocculating agent such as an acrylamide polymer (which term includes a copolymer). Suitable polyacrylamides are available under the trade mark "Percol" (Allied Colloids). Good results have been obtained both with anionic flocculating agents and with cationic flocculating agents. In other preferred embodiments, and as described in greater detail hereinafter, the flocculating agent is constituted, wholly or in part, by the same agent or combination of agents that constitutes the component (c).

The filler flocs should not be so large that they become visible to the naked eye in the final product or that they interfere with fibre-fibre bonding and thus adversely affect product performance. Floc size is influenced by various factors, including the amount of flocculating agent and the shear forces to which the filler composition is subjected. Control of such factors is entirely conventional, although, as a guide, the amount of flocculating agent will be usually in the range from 0.01 to 3.0% active substance, preferably from 0.01 to 0.1%, by weight of the filler.

It seems preferable to use, as component (b), fibres that have an average length greater than that of the fibres that constitute the matrix of the fibrous sheet material (i.e. the fibres in the stock to which the filler composition is to be added).

It is preferred that the synthetic organic fibres used as component (b) should have an average length of at least 4 mm. (In contrast, cellulosic papermaking fibres commonly have an average fibre length of 0.5 to 3.5 mm.) Commonly, the fibres in component (b) will have an average length of at least 5 or 6 mm and typically up to 26 mm, although fibres having an average length exceeding 26 mm could be used, notably in wet-laid nonwovens.

Particularly preferred average fibre lengths are in the range from 4 to 12 mm for paper and board uses.

Fibre thickness (i.e. fibre diameter in the case of fibres having a circular cross-section) is preferably from 1 to 50  $\mu\text{m}$ , especially from 5 to 40  $\mu\text{m}$ . Fibres having a non-circular cross-section and/or having an uneven (e.g. rough or crinkled) surface can also be used as component (b). For example, water-dispersible synthetic polymer fibre of cruciform cross-section is disclosed in US-A 4 713 289 filed in 27 March 1986 and the corresponding EP-A 0 198 401, whereas water dispersible synthetic polymer fibre of scalloped-oval cross-section is disclosed in US-A 4 707 407 filed 27 March 1986 and the corresponding EP-A 0 998 400. The teaching of the aforesaid applications is incorporated herein by reference.

It is believed that the fibres of non-circular cross-section may offer additional resistance against deflocculation, since the projections (e.g. crests, ridges or lobes) in the fibres may protect the recesses (e.g. valleys, indentations or "saddles") in the fibres from the high shear forces that may be experienced in various zones of the sheet-making system. An uneven fibre surface may also offer protection against the possible stripping of the coupling agent (c) from the fibres by such shear forces.

Component (b) is not limited to true cut fibres but may include or consist of fibrils or other branched or fibrillated species, and the term "fibre" in the context of component (b) is to be construed accordingly. The fibrils or the fibrils (which could be shorter than 4 mm) may have a high surface area and may be capable of self-cohesion and of entrapping filler particles or flocs, thereby enhancing the coupling action and tending to inhibit later deflocculation or decoupling.

The fibres to be included in the filler composition as component (b) are synthetic organic fibres (which expression herein includes any suitable man-made fibre or regenerated fibre), amongst which polyester fibres (e.g. poly(ethylene terephthalate)), for example those marketed under Du Pont's registered trade mark "Dacron", and aramid (aromatic polyamide) fibres or fibrils, for example those marketed under Du Pont's registered trade mark "Kevlar", have been found to be particularly good. However, other fibres, such as polyamides (e.g. nylon), polyolefins (e.g. polyethylene or polypropylene), acrylics, cellulose acetates, viscose rayon, polyimides and copolymers, can be used.

The synthetic organic fibres (b) may have a surface pretreatment before they are incorporated into the filler composition. Synthetic fibres tend to be hydrophobic but can be rendered hydrophilic by appropriate treatment. Thus, the pretreatment is preferably such that the dispersibility of the fibres in water is improved and the application of a surface coating containing polyoxyalkylene groups, notably polyoxyethylene groups, has been found to be suitable. Man-made organic fibres, in particular polyester fibres, with a coating comprising segmented polyethylene terephthalate/polyethylene oxide block copolymer, are especially preferred.

Suitable surface-pretreatments have been disclosed by Ring et al in US-A 4 007 083, by Hawkins in US-A 4 137 181, US-A 4 179 543 and US-A 4 294 883, and in GB-A 958 350 (Viscose Suisse) and JP-A 58 208 499 (Teijin), the teaching of which patent documents is incorporated herein by reference.

The present Applicants consider that the presence of gel particles in any significant quantity could be detrimental in the present compositions since they would spoil the appearance and performance of the paper or other sheet product. Accordingly, the binding of fibres to filler particles by means of gel particles that enclose the filler particles and that are formed by coagulation and subsequent sub-division of a continuous phase in which the filler particles are dispersed, in the manner disclosed in US-A 2 027 090 is not contemplated as "coupling" in the context of this invention.

The coupling agent (c), which (subject to the preceding disclaimer) bonds, bridges, links, or otherwise attaches the filler particles and/or flocs to the fibres (b) (the term "coupling agent" not of itself implying herein any particular mechanism for the fibre-filler attachment), will usually be selected from polymers (which term in this context includes oligomers, such as dimers, trimers and tetramers, as well as species with higher degrees of polymerisation) containing functional groups that are substantive to the filler and functional groups substantive to the fibre (b). Such functional groups include hydroxyl, carboxyl, carboxylic anhydride and ketene groups. The polyhydroxy substances have proved particularly suitable, e.g. polysaccharide-based substances such as starch, mannogalactans and the like, and their derivatives. Usually agents that are hydrophilic, especially those that are soluble or colloiddally dispersible in water, are used.

Preferred coupling agents may be selected from starches and modified starches (e.g. cationic or amphoteric starch), cellulose ethers (e.g. carboxymethyl cellulose (CMC)) and derivatives thereof; alginates; cellulose esters; ketene dimers; succinic acid or anhydride polymers; natural gums and resins (especially mannogalactans, e.g. guar gum or locust bean gum) and the corresponding modified (e.g. cationic or amphoteric) natural gums and resins (e.g. modified guar gum); proteins (e.g. cationic proteins),

for example soybean protein; poly(vinyl alcohol); and poly(vinyl acetate), especially partially hydrolysed poly(vinyl acetate). The coupling agents will, for the most part, also act as viscosity boosters and stabilisers, and they may act to improve the hydrophilicity of the fibres.

Cationic starch has been found to be particularly effective as a coupling agent. Cold-water-soluble cationic starch is available under the trade marks "Perfectamyl PLV" (Tunnel Avebe Starches Ltd) and "Solvitose D9" (AB Stadex). Cationic starches that require cooking in order to form an aqueous solution (referred to as "cooked starches" hereinafter) are available under the trade marks "Raisio RS 180", "Raisio RS 190" (Raisio AB) and "Posamyl L7". An amphoteric starch is available under the designation SP-190 (Raisio AB).

Preferably, the cationic starches will have a degree of substitution of at least 0.02, typically from 0.02 to 0.1.

Modified guar gum, for example the amphoteric guar gum that which is available from Meyhall Chemicals under the trade mark "Meyprobond 120", is effective too and has the advantage that it also acts as a flocculating agent for the filler particles. (Cationic starch at a level of 0.5-3% also flocculates filler particles, but the resultant flocs tend to be weak unless a stronger flocculant, such as a polyacrylamide, is also used.) Cationic guar gums are available under the trade marks "Meyproid 9801" (Meyhall AG), "Gendriv 158" and "Gendriv 162" (Henkel Corporation).

Sodium carboxymethylcellulose also works well as a coupling agent, but is sensitive to the papermakers' alum (aluminium sulfate) used in conventional alum/rosin sizing agents. (CMC is a carbohydrate-based substance, as are cationic starch, modified guar gum and alginates; however, as indicated above, substances that are not based on carbohydrates are also useful herein.) It may be advantageous to cationize the coupling agent, notably CMC or an alginate - e.g. by means of dimethyl diallyl ammonium chloride, polyamine-epichlorohydrin and like agents - since cationic polymers are expected to couple more effectively the fibres (b) to the filler particles, which fibres and particles will generally acquire an anionic character in aqueous dispersion.

The coupling agents (c) are not restricted to organic polymers alone. Colloidal silicic acid and bentonite (both of which may be regarded as polyhydroxy compounds when in an aqueous medium) have been described as "anionic polymers" in the literature (see International Patent Specification No. WO 86/05826, page 3, lines 31-32, the teaching of which specification is incorporated herein by reference) and, indeed, these and other colloidal, hydrophilic, inorganic materials, especially polyhydroxy or polyhydrate materials, may be used to increase the efficacy of the coupling agent (c).

A preferred class of such inorganic materials comprises the colloidal silicas, which term herein includes colloidal silicic acid, polysilicic acid and colloidal silica sols. These will generally have a particle size of less than 100 nm, usually from 1 to 50 nm. Suitable silicas are available commercially, e.g. from Eka AB or under the trade mark "Ludox" (Du Pont). The aluminium-modified silicic acid sols (see Ralph K. Iler, "The Chemistry of Silica", John Wiley & Sons, New York, 1979, pages 407-410) also come into consideration.

The colloidal silicas may be used, for instance, in conjunction with such organic substances as carbohydrates (e.g. cationic starch, amphoteric or cationic guar gum or cationic amylopectin) and/or polyacrylamides. Certain combinations of colloidal silicas or Al-modified silicic acid sols with the aforesaid organics have been proposed as binders in papermaking; see US-A 4 385 961, US-A 4 388 150 and US-A 4 643 801, EP-A 0 080 986 and published International Patent Applications No. WO 86/00100 and No. WO 86/05826 (the teaching of which documents is incorporated herein by reference). However, these documents do not appear to disclose or suggest the use of such silicas in systems wherein preferably flocculated filler particles are coupled to synthetic fibres prior to addition of the filler to the papermaking stock with a view to improving tear strength.

The colloidal silica or the combination thereof with an organic substance may also function as a flocculating agent for the filler particles.

Bentonite and similar colloidal clays may also be used in the present invention, preferably in the compositions containing cationic starch or modified guar gum. The bentonite, for example in conjunction with an anionic polyacrylamide, may act as a coagulant or structure improving aid (see J.G. Langley and E. Litchfield, "Dewatering Aids for Paper Application", TAPPI Papermakers Conference, April 1986). Suitable bentonite clays are available under the trade marks "Organosorb" and "Hydrocol" (Allied Colloids) and a suitable anionic polyacrylamide is available under the trade mark "Organopol" (Allied Colloids). Bentonite may also be used in conjunction with substantially non-ionic polymers (such as those described in EP-A-0,017,353 (the teaching of which is incorporated herein by reference)).

A study of the photomicrographs of Figures 2 to 5 and photomicrographs of other fibre/flocculated filler systems according to this invention has revealed that such coupling agents (c) as cationic starch and amphoteric guar gum attach to the surface of polyester fibres (b) and that the (flocculated) filler particles adhere to the coupling agent. The coupling agent has been observed to form a layer, film or coating on the fibre and/or a network or lattice structure attached to the fibre surface (such layers, films, coatings or structures being in some cases discontinuous, patchy or irregular). The attachment of the coupling agent to the fibres has also been shown to occur in the absence of the filler particles (eg. before addition of the latter). Although it is believed that a similar mechanism for the coupling operates for the other coupling agents (c), and with other fibres (b), this has not yet been verified. It is considered sur-

prising that useful coupling of the filler particles to the fibres (b) may be achieved merely by mixing the fibres and the filler particles in an aqueous system containing the coupling agent in solution or colloidal dispersion. Thus the invention avoids the need for such measures as coagulating an entire dispersion and subdividing the resultant gel.

5 In addition to attaching the filler particles or flocs to the fibres (b); the coupling agent (owing, for example, to residual cationicity) may, possibly, form bonds between the resultant filler/fibre aggregates and the fibres (e.g. cellulose fibres) that form the matrix of the fibrous sheet material.

Of course, any of the above-discussed components - the filler (a), the fibre (b), the coupling agent (c) and the flocculating agent (d) - may be composed of a mixture of suitable substances.

10 The filler composition, as added to the fibre slurry from which the fibrous sheet is formed (which slurry is also referred to herein as the stock), will, in general, be in the form of an aqueous dispersion. When preparing the aqueous filler composition, it is desirable to avoid flocculation of the fibres (b), since that could give rise to an unsatisfactory "formation" in the finished sheet. Many of the coupling agents mentioned above do not cause significant flocculation of the fibres (b). Surprisingly, the flocculating agents (d) also appear not to cause significant flocculation of the fibres (b), in particular polyester, aramid and other synthetic fibres; it is thus possible to pre-flocculate the filler in the presence of the fibres (b) and to add the coupling agent subsequently. However, other orders of addition are possible: for example, the fibres (b) can be added to the filler composition after the filler particles have been flocculated; or, as another example, the fibre (b) is added to water, the coupling agent is added next and thereafter the preflocculated filler is admixed. A suitable order of addition for any given set of components can be readily ascertained by simple trials. Of course, the degree of flocculation is affected by other factors, e.g. the time for which, and the energy with which, the system is agitated and the presence of surfactants.

The concentration of filler and of fibre (b) in the aqueous filler composition and the rate at which the latter is added to the stock will depend upon the desired levels of filler and fibre (b) in the finished sheet product. The level of filler is usually from 3 to 80%, preferably from 5 to 50%; the level of fibre (b) is usually from 0.5 to 60%, preferably from 20 to 60% in the case of wet-laid nonwovens or preferably from 1 to 25% and typically from 1 to 5%, in the case of other products, such as paper or board; and the level of coupling agent is usually from 0.01 to 5%, preferably from 0.1 to 5%, the aforesaid percentages being by weight of the finished, dry sheet product.

Although the present invention may be utilised in the manufacture of such fibrous sheet materials as nonwovens, paperboards and composites, it is of particular benefit in the manufacture of paper, especially the commodity papers such as supercalendered paper, magazine paper, newsprint, packaging paper and coated papers, as well as speciality papers. The grammage of the sheet material may vary, depending upon its intended use, but these days will typically be from 45 to 400 g/m<sup>2</sup>.

Depending, of course, on the intended application and on economic considerations, the fibrous sheet materials will usually be composed primarily of cellulosic fibres, in particular the fibres obtained from vegetable sources, especially wood. Thus, the furnishes used in the production of the fibrous sheet materials may comprise a pulp containing hardwood fibres, softwood fibres or a mixture thereof, and which may be a mechanical, chemimechanical, semichemical or chemical pulp, or may comprise recycled or secondary fibres with or without organic fillers. It is also possible to employ cellulose fibres from nonwood vegetable sources, such as cotton, bagasse, esparto, straw, reed or Manila hemp, either alone or as a blend with wood pulp. The so-called synthetic pulps, for example the fibrillated polyolefin materials, also come into consideration; however, for reasons of cost, these will usually be used with a pulp of vegetable origin. Other fibrous materials may be included in the furnish, e.g. rayon, nylon, aramid, alginate, poly(vinyl alcohol), polyacrylic, polyolefin or copolymer fibres.

The furnish may include any of the conventional papermaking additives, for example drainage aids, de-foaming agents, wet-strength additives, dry-strength additives, pitch control agents, slimicides, stabilising agents such as sodium silicate and sizing agents.

50 The addition to the stock of acrylic polymer latex binders, which are hydrophobic and generally require the use of a special dispersant or emulsifier, is not favoured in this invention, since such binders prevent useful recycling in the sheet-making system. The use of such latexes is not however precluded in a coating mix applied after the web has been formed and dried.

Sizing treatment may be effected either by "internal" sizing or by "surface" sizing to render the paper or other sheet material partially hydrophobic. Suitable sizing agents include the conventional rosin/alum systems (although these may preclude the use of acid-reactive fillers such as untreated calcium carbonate), the cellulose-reactive sizing agents such as those based on the long-chain alkylketene dimers (which permit sizing in neutral or alkaline conditions), wax emulsions, succinic acid derivatives, polyalkylene imines and various fluorochemicals.

60 The inclusion of a ketene dimer in the furnish may be particularly advantageous, in that it can improve the folding endurance of paper and board manufactured in accordance with this invention; this could find use, for example, in a multiply board, where it may be possible to include the filler composition of this invention in only one of the layers. It has also been found that a ketene dimer, especially when used in conjunction with a cellulose ether (preferably carboxymethyl cellulose), starch or a starch derivative, can significantly improve the wet strength of the fibrous sheet product. Thus, it may be possible to pro-

duce a coated label paper with enough wet strength for it to pass through a bottle-washing plant (e.g. in a brewery) while still allowing the mill to recycle its dry broke without chemical treatment or an excessive consumption of energy.

5 The procedures and apparatus for preparing, conveying and diluting the stock and for preparing the fibrous sheet material from the stock may be entirely conventional. Such procedures and apparatus are well documented (see, for example, the article entitled "Paper" in the Kirk-Othmer Encyclopedia referred to above) and a detailed discussion herein is considered to be superfluous. It is preferred, however, that the sheet be formed on a continuous or intermittent machine, for example a cylinder machine (VAT), a Fourdrinier machine, a machine having multi-wire formers or an inclined wire machine (as commonly  
10 used to produce wet-laid non-wovens).

The (preferably preflocculated) filler composition should be added to the stock at a point in the system which permits the filler particles (or flocs) and the associated fibres (b) to be uniformly distributed in the stock by the time it reaches the web-forming zone; accordingly, the filler composition will normally be added to the furnish before it reaches the flowbox (or headbox) of the papermaking machine. It is also preferred to add the filler composition to the pulp after it has left the beater, since the high-shear conditions that obtain in the beater could break or deform the synthetic organic fibres and/or other fibres used as component (b) and could also cause deflocculation of the filler flocs (agglomerates). It is particularly preferred to add the filler composition to the stock just before the main fan pump, especially at the stock inlet of the main fan pump (being the pump that propels the stock to the flowbox of the machine).  
15

20 The subsequent addition (e.g. prior to the flowbox) of a further amount of any of the components of the present compositions, especially the flocculating agent and/or the coupling component, is not precluded. Indeed, such additions may be beneficial in repairing any deterioration in properties due, for example, to exposure of the coupled fibre/filler complex to excessive shear forces. Microscopic analysis of samples has suggested that the coupling agent and filler particles or flocs can be disturbed, and even  
25 peeled away from the fibres, by excessive shear forces, e.g. in the cleaners. Addition of the flocculant and/or of the colloidal inorganic material separately from the filler composition could also be tried.

As mentioned above, dry or concentrated-liquid formulations may be provided from which aqueous compositions containing the, preferably preflocculated, filler can be prepared. For example, a single formulation, or "pack", may contain filler particles, a flocculating agent for the particles, fibres (b), and a coupling agent in appropriate proportions; it is here possible to employ a polymeric material, e.g. modified guar gum, that will function both as the flocculant and as the coupling agent. Alternatively, since fibres suitable for component (b) are readily available, the pack could contain just the filler, flocculating agent and coupling agent. Although the simultaneous dispersion in water of the components when using such a pack may not give optimum results, this may be compensated for by the increased convenience to the manufacturer of the fibrous sheet material. It is, of course, also possible to use multi-part packs, e.g. a  
30 two-part pack containing the filler and flocculating agent in one part and the fibre (b) and coupling agent in the other.

The present invention is illustrated in and by the following specific examples.

#### 40 Example 1

Several series of tests were carried out using the following experimental procedure.

#### 45 Preparation of Stock

A mixture of 70% bleached eucalyptus Kraft and 30% bleached softwood Kraft was treated in a Valley beater at 1.57% consistency to give a stock with a Canadian Standard Freeness in the range 350 to 450°. Portions of stock containing 24g (oven-dry basis) of cellulose fibre were withdrawn and disintegrated in a British Standard disintegrator for 15,000 revolutions.  
50

#### Preparation of filler composition

Each preflocculated filler composition was prepared as an aqueous suspension, using a small stirrer to agitate the suspension continuously. Various orders of addition of the components were tried, a typical procedure being as follows:  
55

The fibre (b) was dispersed in approximately 500 ml water in a preparation vessel. The appropriate volume of a 1% solution of coupling agent (e.g. cationic starch) was added. An aqueous slurry of filler was made and added to the preparation vessel after the coupling agent. A dilute solution of flocculating agent (e.g. Percol 292) was thereafter added slowly.

60 The other orders of addition, which are shown in the Tables of results hereinafter, were effected by procedures analogous to that described above. (This should not, of course, be taken as precluding other orders of addition, e.g. addition of the dry compositions to the stock.)

Production of handsheets

The filler composition was added to the stock and mixed therewith by hand. The resultant suspension was diluted to approximately 0.3% consistency. A total volume of 3 litres of stock was employed in a British Standard sheet-making machine to form handsheets having a grammage of about 70g/m<sup>2</sup> (oven-dry basis). The stirrer was placed in the machine to act as a baffle before the addition of the stock. In the tests in Series 09 and subsequent series the sheet machine was modified, with the intention of increasing the filler retention, by using a restricted throat in order to retard the rate of drainage during formation of the sheet and by replacing the needle valve by an open hose, thereby reducing the vacuum applied to the sheet.

Components

A polyester fibre that is commercially available under Du Pont's registered trade mark "Dacron" was employed as the fibre (b) in all but one of the tests in this Example, this polyester fibre having an average fibre length (cut length) of 6 mm and an average fibre diameter of 13 µm.

In Test 05/E3, however, the fibre (b) was a polyester fibre of scalloped-oval cross-section as described in U.S. Patent Application 842,790, the fibre having a cut length of 6 mm.

The fillers were whiting (specifically a ground calcium carbonate supplied under the trade name "Britomya V" or "Britomya S") and kaolin (grade C, from English China Clays).

The flocculating agents were a cationic high-molecular-weight polyacrylamide (supplied by Allied Colloids under the trade mark Percol 292), an anionic high-molecular-weight polyacrylamide (supplied by Allied Colloids under the trade mark Percol 155) and an amphoteric mannogalactan (supplied by Meyhall Chemicals under the trade mark Meyprobond 120 EV, which material also functioned as a coupling agent).

The coupling agents, in addition to the amphoteric mannogalactan, were CMC, a ketene dimer (supplied by Tenneco Malros under the trade mark Keydime DX4), cationic starch (supplied by Tunnel Avebe Starches Ltd. under the trade mark Perfectamyl PLV), calcium alginate and ammonium alginate.

The cationising agent, when used, was a polyamine-epichlorohydrin supplied by Allied Colloids under the trade mark Percol 1597. In certain tests, papermakers' alum was used to buffer the stock.

Testing of the sheets

The handsheets were air-dried and conditioned at 20°C and 65% relative humidity before being tested.

The grammage was determined in g/m<sup>2</sup> on an oven-dry basis.

The level of retained filler was measured by ashing the sheets at 925°C for one hour and is expressed as a percentage by weight. Where whiting was employed as the filler, the ash (calcium oxide) was calculated to percent calcium carbonate.

The breaking length (expressed in km), the burst factor, the tear factor and the apparent density (expressed in kg/m<sup>3</sup>) were determined by standard procedures.

The opacity of the sheets was determined by the International Standards Organization (ISO) method, the results in all cases being corrected to a basis weight of 70 g/m<sup>2</sup>.

The air porosity was measured by the Gurley 20 ounce densometer method and is expressed in s/100cm<sup>3</sup> air.

The tests, as mentioned above, were carried out in series. The sheets prepared in the tests with in each series were prepared from a single beating of cellulose pulp; direct comparisons could therefore be made within each series. However, in order to compare results from different series, a parameter is required that is independent of the freeness of the stock. Such a parameter is the residual strength factor or RSF, which is defined as follows:

$$RSF = \frac{S(1)}{S(0)} \times 100$$

where  $S(0) = \frac{\text{Tear} \times \text{Tensile}}{\text{Grammage}}$

for a virgin fibre control furnish, and

$$S(1) = \frac{\text{Tear} \times \text{Tensile}}{\text{Grammage}}$$

Grammage

for a test furnish.

Tear : Marx-Elmendorf tear reading in gf.

Tensile : Schopper tensile reading in kgf.

Grammage : Oven-dry in g/m<sup>2</sup>.

In some experiments, just the parameter S(1) was determined (this being termed the "strength factor") in the absence of a virgin fibre control furnish.

#### Control Tests

In order to ascertain clearly the effect of adding the polyester fibre, control tests were carried out using filler compositions from which the polyester fibre was omitted. For a proper comparison, it was necessary to ensure that the grammage and the filler content of the sheet produced in a control test were substantially the same as those of the sheet produced in the corresponding test according to the present invention. Rather than adjust the composition of the fibre furnish, it was found that the grammage and filler content could be regulated more accurately in the control tests by substituting for the polyester a volume of pulp stock containing the same weight of cellulose fibre and diluting that volume to 500 ml. Thus, the design of the control tests was a consequence of the laboratory-scale procedures used in this example and, accordingly, these control tests are not intended to represent a technique known in the prior art.

#### Test results

For brevity, only a selection of the results are shown in the following Tables, which results have been selected primarily to illustrate the various combinations of components that were investigated.

Each test is identified by a number, the first two digits of which refer to the series. The letter C denotes a control test and is followed by the identification number within the particular series, whereas the letter E denotes a test according to the present invention and is also followed by an identification number within the appropriate series. The amount of polyester is expressed as a percentage by weight on the cellulose fibre; the amount of filler (whiting or kaolin) is expressed as a percentage by weight on total fibre; the amount of Percol 292 is expressed as a percentage by weight on the total of fibre and filler; the amount of each remaining additive is expressed as a percentage by weight on the total furnish; and the test results are expressed, where appropriate, in the units mentioned above.

The numbers in brackets refer to the order of addition in the preparation of the filler composition; in certain cases, some components were pre-mixed, giving identical numbers, whereas in certain other cases a component was added in two portions, giving two numbers for that component.

### Discussion

The experimental results show that the tearing resistance of the paper hand sheets was improved by the inclusion of the polyester fibre. Thus, taking two systems having similar retained-filler contents, the paper sheet of Test 04/E3 had a tear factor of 118, whereas that of Control test 04/C4 had a tear factor of only 91; similarly, the handsheet of Test 05/E1 showed a tear factor of 113, whereas that of Control Test 05/C2 had a tear factor of only 82. The results obtained from Tests 08/E1-08/E4 suggest that the tear factor increases in relation to the proportion of polyester fibre in the furnish.

The experimental results also indicate that the presence of the polyester fibre reduces the apparent

density of the sheet (i.e. increases the bulk) while improving the air porosity. Thus, the apparent density in Test 04/E3 is 605 kg/m<sup>3</sup>, compared with 661 kg/m<sup>3</sup> in Control Test 04/C4, and the Gurley air porosity in Test 04/E3 is 6.9 s/100 cm<sup>3</sup> air, compared with 14 s/100 cm<sup>3</sup> air in Control Test 04/C4. Similarly, compared with Control Test 05/C2, Test 05/E1 shows a lower apparent density (596 kg/m<sup>3</sup>, as against 668 kg/m<sup>3</sup>) and an improved Gurley air porosity (5.8 s/100 cm<sup>3</sup> air, as against 12 s/100 cm<sup>3</sup> air). These consequences of the inclusion of the fibre (b) in accordance with the present invention are expected to increase the runnability of the sheet-making machine and to decrease the load on the drying cylinders, thereby reducing the process costs.

Tests 07/E1-E4 demonstrated that, in the practice of this invention, the polyacrylamide used as the flocculating agent and retention aid could be reduced: although the filler content of the handsheets was decreased, the filler flocs were less intrusive (due to smaller size) and the appearance of the handsheets was more acceptable.

In these experiments, the anionic polyacrylamide (Percol 155) was found to be a more effective flocculating agent than the cationic polyacrylamide (Percol 292). Thus, large flocs were present in the sheet prepared in Test 08/E8.

Analysis of the results in Tests 11/E4 and the corresponding controls 11/C3-11/C6 shows that an increase in the quantity of cationic starch in the filler system increases the residual strength of the resultant sheet up to an optimum starch addition of 1.5%. However, this is due primarily to the effect of the starch on the burst and tensile strengths, whereas the handsheets prepared from a stock to which polyester fibre was added in accordance with the present invention showed a significant improvement in tearing resistance.

In Tests 12/E1 and 12/E3, when the same quantity of clay was substituted for whiting, the retained filler content and strength of the sheets were similar. However, when the papermakers' alum (aluminium sulfate) was added to reduce the pH (as could occur when using a rosin-based sizing agent), the sheet strength was reduced. This suggests that in practice, a neutral sizing system (e.g. ketene dimer) may prove preferable.

Although all of the coupling agents tested could be utilised with the polyester fibre as an additive to the filler composition, the results suggest that CMC and cationic starch were the most effective for the purpose of maintaining the strength of the filled paper sheets. The results also indicate that the amphoteric mannogalactan (Meyprobond 120EV) could function as both the flocculating agent and the coupling agent. Thus, even at a level of 0.1%, the amphoteric mannogalactan enabled the retention of more than 20% filler, but higher strengths were obtained at levels of 0.5 to 1% of that additive.

Of course, as the filler becomes dominant in the sheet (about 40% filler) the improvement in the residual strength factor due to the inclusion of the fibre (b) in accordance with this invention becomes less marked. Nevertheless, even at the high filler levels shown in Test 13/E4 and Control Test 13/C4, the polyester-containing sheet in accordance with this invention still shows an 8.7% advantage (the difference between Tests 13/E4 and 13/C4 expressed as a percentage). Furthermore, even at such a high level of filler, the polyester-containing sheet prepared in accordance with this invention maintains a surprisingly high bulk (low apparent density).

## Example 2

Handsheets were prepared using the general procedure described above for Example 1, except that the stock was an Irving bleached softwood Kraft beaten to 440° Canadian standard freeness mixed with recycled fibres (waste newsprint or a mixed white waste). The fibre (b) was the commercially available polyester fibre used in Example 1.

Results are shown in Table 4 hereinafter. The amounts of the stock fibres are expressed as a percentage by weight of the total cellulose fibre; the amounts of the other components and the test results are expressed as in Example 1.

Table 4 (Example 2)

Example 3

Handsheets were prepared using the general procedure described above for Example 1, except that the order of addition of the components of the preflocculated filler composition was as follows:

5

1. 5% of fibre (b) by weight of the cellulose fibre.
2. 1.5% cationic starch by weight of total furnish.
3. 38.1% filler by weight of total fibre.
4. 0.014% cationic polyacrylamide by weight of total furnish.

10

As in the preceding Examples, the additions are calculated on the basis of oven-dry fibre.

Several series of experiments were carried out using various fibres (b), including not only polyester fibres but also other synthetic fibres and rayon fibres, each of average fibre length exceeding 4mm (except for the polyethylene fibrils of Test 8, which may have been shorter than 4 mm), and using, as the filler, either whiting or kaolin clay (the latter being used in systems containing papermakers' alum). The

15

aramid fibres of Test 10 exhibited fibrillation. The residual strength factor (RSF) and the retained filler content of the handsheets were ascertained, and the results are summarised in the following Table 5.

**Example 4**

Several series of tests were carried out using an experimental procedure analogous to that of Example 1, except as stated below.

**Preparation of stock**

A mixture of 70% bleached eucalyptus Kraft and 30% bleached softwood Kraft was treated in a Valley beater to give a quantity of cellulose stock of Canadian Freeness 400-450°. Each load of pulp from the beater was used to prepare the sets of one series.

**Preparation of filler composition**

Various filler compositions according to this invention were prepared.

A number were prepared by first dispersing the fibre (b) in water, then adding an aqueous solution of

cationic starch (as the coupling agent), an aqueous slurry of filler particles and a dilute solution of a polyacrylamide flocculating agent. In some cases, bentonite was added as the final component of the filler composition.

Others of the compositions were prepared by a similar procedure, but omitting the bentonite and substituting colloidal silica for the polyacrylamide.

The components (and their order of addition) of the remaining compositions will be clear from Tables 6 and 7 hereinafter.

#### Production of handsheets

The filler composition was added to a portion of the cellulose stock and diluted to a total volume of 8 litres. The diluted stock was used to form handsheets in a British standard sheet-making machine.

#### Components

The fibre (b) was a polyester fibre commercially available under the trade mark "Dacron" (Du Pont) and having an average cut length of 6 mm and an average fibre diameter of 13  $\mu$ m.

The filler was a ground calcium carbonate supplied under the trade name "Britomya M".

The cationic starch was selected from the cold-water-soluble starches sold under the trade names "Perfectamyl PLV" (degree of substitution, d.s. - 0.035) and "Solvitose D9" (d.s. 0.100) and the cooked starches "Raisio RS 180" (d.s. 0.035), "Raisio RS 190" (d.s. 0.042) and "Posamyl L7" (d.s. - 0.048).

The flocculating agent was selected from the cationic high-molecular-weight polyacrylamides "Percol 292" and "Percol 63" and the anionic high-molecular weight polyacrylamide "Percol 155" (all from Allied Colloids).

The colloidal silica was selected from Ludox (trade mark) HS 40 (Na as counterion, negative particle charge, average particle diameter 12 nm) from Du Pont and "Silica BMA", being a silica of the type used in the Eka "Composil" (trade mark) process. The bentonite was an amphoteric bentonite clay supplied under the trade name "Hydrocol O" by Allied Colloids.

#### Testing of the sheets

The testing was carried out using the procedures described in Example 1.

#### Test results

For brevity, only a selection of the results are shown in Tables 6 and 7 which follow, which results are intended primarily to illustrate the various combinations of components that were investigated.

Each test is identified by a number, the first number indicating the series and the rest indicating the number of the test within that series.

The amount of polyester fibre is expressed as a percentage by weight on the cellulose fibre; the amount of filler is expressed as a percentage by weight on the total fibre; and the amount of each remaining component is expressed as a percentage by weight on the total furnish. Numbers in brackets refer to the order of addition in the preparation of the filler composition.

Further Discussion

In Example 4, as in the previous Examples, the filler compositions were prepared under normal ambient conditions, such as room temperature. In the Examples, the tests were on a laboratory scale. However, pilot runs on a continuous paper machine have indicated the feasibility of using the present invention on a commercial scale. The pilot runs employed a 70% bleached birch/30% bleached pine kraft as the cellulose stock and calcium carbonate as the filler; the flocculating agent (retention aid) was selected from Percol 292 and Percol 63; the coupling agent was selected from cold-water soluble starch, cooked starch, CMC and amphoteric guar gum; and the synthetic fibre was Dacron (trade mark) polyester, 6 mm average fibre length. Percol 1597 was used as a cationizing agent.

In certain of the tests in Example 4, the resultant sheet showed evidence of over-flocculation. However, it is believed that this is unlikely to cause problems in a paper mill owing to the high shear conditions prevailing therein. Indeed, significant problems of overflocculation were not encountered in the pilot scale runs referred to above.

**Claims**

1. A filler-containing composition suitable for use in the manufacture of fibrous sheet materials and which comprises (a) filler particles, characterised in that it also comprises (b) synthetic organic fibres, and (c) a polymeric material that functions as a coupling agent between the filler particles and the said fibres (b).
2. A composition according to claim 1, characterised in that the filler is clay, talc or calcium carbonate.
3. A composition according to claim 1 or 2, characterised in that the synthetic organic fibres (b) have an average length of 4 mm or more.
4. A composition according to claim 1, 2 or 3, characterised in that the fibres (b) are selected from polyester fibres and aramid fibres or fibrils.
5. A composition according to any one of claims 1 to 4, characterised in that the fibres (b) have a surface coating comprising polyoxyalkylene groups.
6. A composition according to claim 5, characterised in that the coating comprises segmented polyethylene terephthalate/polyethylene oxide block copolymer.
7. A composition according to any one of claims 1 to 6, characterised in that the polymeric material (c) is of itself soluble or colloidal dispersible in water.
8. A composition according to any one of claims 1 to 7, characterised in that the polymeric material (c) is a polymer selected from starches, modified starches, cellulose ethers and derivatives thereof, alginates, cellulose esters, ketene dimers, succinic acid polymers, natural gums and resins, modified natural gums, modified natural resins, proteins, poly(vinyl alcohol) and poly(vinyl acetate).
9. A composition according to claim 8, characterised in that the said polymer is a cationic starch, carboxymethylcellulose, cationized carboxymethylcellulose or a modified mannogalactan gum.
10. A composition according to any one of claims 1 to 9, characterised in that the coupling component (c) also acts as a flocculating agent for the filler particles.
11. A composition according to claim 10, characterised in that the coupling component (c) is a modified guar gum or cationic starch.
12. A composition according to any one of claims 1 to 11, characterised in that it also contains (d) a flocculating agent for the filler particles.
13. A composition according to claim 12, characterised in that the flocculating agent (d) is a polyacrylamide.
14. A composition according to any one of claims 1 to 13, characterised in that it also contains (e) a colloidal inorganic polyhydroxy or polyhydrate compound.
15. A composition according to claim 14, characterised in that the component (e) is selected from colloidal silicas and colloidal bentonite clays.
16. A composition according to any one of claims 1 to 15, characterised in that it is an aqueous composition.
17. A process for the manufacture of a fibrous sheet material by dewatering an aqueous slurry of fibres, wherein a composition that contains (a) filler particles is added to the slurry of fibres before the dewatering commences, characterised in that the said filler-containing composition also comprises (b) synthetic organic fibres and (c) a polymeric material that functions as a coupling agent between the filler particles and the said fibres (b).
18. A process according to claim 17, characterised in that the filler-containing composition is according to any one of claims 2 to 16.
19. A process according to claim 17 or 18, characterised in that the fibrous sheet material is manufactured by the draining of water from a slurry comprising cellulose fibres.
20. A process according to claim 17, 18 or 19, characterised in that the aqueous slurry of fibres also contains a ketene dimer sizing agent.
21. A process according to any one of claims 17 to 20, characterised in that there are introduced into the fibrous sheet filler particles in an amount of from 3 to 80%, the fibre (b) in an amount of from 0.5 to

60%, and the coupling agent in an amount of from 0.01 to 5.0%, the percentages being by weight of the dry sheet material.

22. A fibrous sheet material that comprises a matrix of first fibres having distributed therein (a) filler particles and (b) second fibres selected from synthetic organic fibres, characterised in that the particles (a) and fibres (b) are in the form of a composition according to any one of claims 1 to 15.

23. A fibrous sheet material according to claim 32, characterised in that the filler particles are flocculated.

24. A fibrous sheet material according to claim 22 or 23, characterised in that it is a paper, a board or a wetlaid nonwoven.

## Patentansprüche

1. Füllstoff-enhaltende Zusammensetzung, geeignet für die Verwendung bei der Herstellung von fasrigen Blattmaterialien, enthaltend (a) Füllstoffteilchen, dadurch gekennzeichnet, dass sie auch (b) synthetische organische Fasern und (c) ein polymeres Material enthält, welches als Kupplungsmittel zwischen den Füllstoffteilchen und den genannten Fasern (b) wirkt.

2. Zusammensetzung nach Anspruch 1, dadurch gekennzeichnet, dass der Füllstoff Ton, Talkum oder Calciumcarbonat ist.

3. Zusammensetzung nach Anspruch 1 oder 2, dadurch gekennzeichnet, dass die synthetischen organischen Fasern (b) eine Durchschnittslänge von 4 mm oder mehr haben.

4. Zusammensetzung nach Anspruch 1, 2 oder 3, dadurch gekennzeichnet, dass die Fasern (b) ausgewählt sind aus Polyesterfasern und Aramidfasern oder -fibrillen.

5. Zusammensetzung nach einem der Ansprüche 1 bis 4, dadurch gekennzeichnet dass die Fasern (b) einen Oberflächenüberzug haben, der Polyoxyalkylengruppen enthält.

6. Zusammensetzung nach Anspruch 5, dadurch gekennzeichnet, dass der Überzug segmentierte Polyethylenterephthalat/Polyethylenoxid-Blockcopolymeren enthält.

7. Zusammensetzung nach einem der Ansprüche 1 bis 6, dadurch gekennzeichnet dass das polymere Material (c) in Wasser löslich oder kolloidal dispergierbar ist.

8. Zusammensetzung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet dass das polymere Material (C) ein Polymeres ist, ausgewählt aus Stärken, modifizierten Stärken, Zelluloseethern und Derivaten derselben, Alginaten, Zelluloseestern, Ketendimeren, Bernsteinsäurepolymeren, natürlichen Gummis und Harzen, modifizierten natürlichen Gummis, modifizierten natürlichen Harzen, Proteinen, Poly(vinylalkohol) und Poly(vinylacetat).

9. Zusammensetzung nach Anspruch 8, dadurch gekennzeichnet, dass das Polymere eine kationische Stärke, Carboxymethylzellulose, kationisierte Carboxymethylzellulose oder ein modifizierter Mannogallactangummi ist.

10. Zusammensetzung nach einem der Ansprüche 1 bis 9, dadurch gekennzeichnet dass die Kupplungskomponente (c) auch als Ausflockungsmittel für die Füllstoffteilchen wirkt.

11. Zusammensetzung nach Anspruch 10, dadurch gekennzeichnet, dass die Kupplungskomponente (C) ein modifizierter Guargummi oder kationische Stärke ist.

12. Zusammensetzung nach einem der Ansprüche 1 bis 11, dadurch gekennzeichnet, dass sie auch (d) ein Ausflockungsmittel für die Füllstoffteilchen enthält.

13. Zusammensetzung nach Anspruch 12, dadurch gekennzeichnet, dass das Ausflockungsmittel (d) ein Polyacrylamid ist.

14. Zusammensetzung nach einem der Ansprüche 1 bis 13, dadurch gekennzeichnet dass sie auch (e) eine kolloidale anorganische Polyhydroxy- oder Polyhydratverbindung enthält.

15. Zusammensetzung nach Anspruch 14, dadurch gekennzeichnet, dass die Komponente (e) ausgewählt wird aus kolloidalen Siliciumdioxiden und kolloidalen Bentonittonen.

16. Zusammensetzung nach einem der Ansprüche 1 bis 15, dadurch gekennzeichnet dass es eine wässrige Zusammensetzung ist.

17. Verfahren zur Herstellung eines fasrigen Blattmaterials durch Entwässerung einer wässrigen Aufschlämmung von Fasern, bei dem eine Zusammensetzung, die (a) Füllstoffteilchen enthält, der Aufschlämmung der Fasern zugesetzt wird, bevor die Entwässerung beginnt, dadurch gekennzeichnet, dass die Füllstoff-enhaltende Zusammensetzung auch (b) synthetische organische Fasern und (c) ein polymeres Material enthält, welches als Kupplungsmittel zwischen den Füllstoffteilchen und den genannten Fasern (b) wirkt.

18. Verfahren nach Anspruch 17, dadurch gekennzeichnet, dass die Füllstoff-enhaltende Zusammensetzung eine gemäß einem der Ansprüche 2 bis 16 ist.

19. Verfahren nach Anspruch 17 oder 18, dadurch gekennzeichnet, dass das fasrige Blattmaterial durch Abziehen von Wasser aus einer Zellulosefasern enthaltenden Aufschlämmung hergestellt wird.

20. Verfahren nach Anspruch 17, 18 oder 19, dadurch gekennzeichnet, dass die wässrige Aufschlämmung von Fasern auch ein Ketendimeres als Schlichte enthält.

21. Verfahren nach einem der Ansprüche 17 bis 20, dadurch gekennzeichnet, dass in das fasrige Blattmaterial Füllstoffteilchen in einer Menge von 3 bis 80%, die Faser (b) in einer Menge von 0,5 bis

60% und das Kupplungsmittel in einer Menge von 0,01 bis 5,0% eingeführt werden, wobei Prozentangaben Gewichtsangaben sind, die sich auf das trockene Blattmaterial beziehen.

22. Fasriges Blattmaterial, das eine Matrix von ersten Fasern enthält, in denen (a) Füllstoffteilchen und (b) zweite Fasern, ausgewählt aus synthetischen organischen Fasern, verteilt sind, dadurch gekennzeichnet, dass die Teilchen (a) und die Fasern (b) in Form einer Zusammensetzung gemäss einem der Ansprüche 1 bis 15 vorliegen.

23. Fasriges Blattmaterial gemäss Anspruch 22, dadurch gekennzeichnet, dass die Füllstoffteilchen ausgeflockt sind.

24. Fasriges Blattmaterial gemäss Anspruch 22 oder 23, dadurch gekennzeichnet, dass es ein Papier, ein Karton oder ein nassabgelegter Vliesstoff ist.

## Revendications

1. Une composition contenant une charge, utilisable dans la fabrication de matériaux fibreux en feuille, et qui comprend (a) des particules de charge, caractérisée en ce qu'elle comprend également (b) des fibres organiques synthétiques et (c) une matière polymère qui agit comme un agent de couplage entre les particules de charge et lesdites fibres (b).

2. Une composition selon la revendication 1, caractérisée en ce que la charge est de l'argile, du talc ou du carbonate de calcium.

3. Une composition selon la revendication 1 ou 2, caractérisée en ce que les fibres organiques synthétiques (b) ont une longueur moyenne de 4 mm ou plus.

4. Une composition selon la revendication 1, 2 ou 3, caractérisée en ce que les fibres (b) sont choisies parmi les fibres de polyester et les fibres ou fibrilles d'aramide.

5. Une composition selon l'une quelconque des revendications 1 à 4, caractérisée en ce que les fibres (b) portent un revêtement de surface comprenant des groupes polyoxyalkylènes.

6. Une composition selon la revendication 5, caractérisée en ce que le revêtement comprend un copolymère segmenté à séquences poly(téréphtalate d'éthylène)/poly(oxyde d'éthylène).

7. Une composition selon l'une quelconque des revendications 1 à 6, caractérisée en ce que la matière polymère (c) est par elle-même soluble ou colloïdalement dispersable dans l'eau.

8. Une composition selon l'une quelconque des revendications 1 à 7, caractérisée en ce que la matière polymère (c) est un polymère choisi parmi les amidons, les amidons modifiés, les éthers de cellulose et leurs dérivés, les alginates, les esters de cellulose, les dimères de cétènes, les polymères d'acide succinique, les gommes et résines naturelles, les gommes naturelles modifiées, les résines naturelles modifiées, les protéines, un alcool polyvinylique et un acétate de polyvinyle.

9. Une composition selon la revendication 8, caractérisée en ce que ledit polymère est un amidon cationique, une carboxyméthylcellulose, une carboxyméthylcellulose cationisée ou une gomme de mannogalactane modifiée.

10. Une composition selon l'une quelconque des revendications 1 à 9, caractérisée en ce que le composant de couplage (c) agit également comme un agent floculant pour les particules de charge.

11. Une composition selon la revendication 10, caractérisée en ce que le composant de couplage (c) est une gomme guar modifiée ou un amidon cationique.

12. Une composition selon l'une quelconque des revendications 1 à 11, caractérisée en ce qu'elle contient également (d) un agent floculant pour les particules de charge.

13. Une composition selon la revendication 12, caractérisée en ce que l'agent floculant (d) est un polyacrylamide.

14. Une composition selon l'une quelconque des revendications 1 à 13, caractérisée en ce qu'elle contient également (e) un composé polyhydroxylé ou polyhydraté minéral colloïdal.

15. Une composition selon la revendication 14, caractérisée en ce que le composant (e) est choisi parmi les silices colloïdales et les argiles bentonites colloïdales.

16. Une composition selon l'une quelconque des revendications 1 à 15, caractérisée en ce qu'il s'agit d'une composition aqueuse.

17. Un procédé pour la fabrication d'un matériau fibreux en feuille par élimination d'eau d'une suspension aqueuse de fibres, dans lequel une composition qui contient (a) des particules de charge est ajoutée à la suspension de fibres avant le commencement de l'élimination d'eau, caractérisé en ce que ladite composition contenant une charge comprend également (b) des fibres organiques synthétiques et (c) une matière polymère qui agit comme un agent de couplage entre les particules de charge et lesdites fibres (b).

18. Un procédé selon la revendication 17, caractérisé en ce que la composition contenant une charge est une composition selon l'une quelconque des revendications 2 à 16.

19. Un procédé selon la revendication 17 ou 18, caractérisé en ce que le matériau fibreux en feuille est fabriqué par l'égouttage d'une suspension comprenant des fibres de cellulose pour en retirer de l'eau.

20. Un procédé selon la revendication 17, 18 ou 19, caractérisé en ce que la suspension aqueuse de fibres contient également un agent d'encollage du type dimère de cétène.

21. Un procédé selon l'une quelconque des revendications 17 à 20, caractérisé en ce, dans la feuille fibreuse, les particules de charges sont introduites en une quantité de 3 à 80%, les fibres (b) en une quan-

tité de 0,5 à 60% et l'agent de couplage en une quantité de 0,01 à 5,0%, les pourcentages étant pris par rapport au poids du matériau en feuille sec.

22. Un matériau fibreux en feuille qui comprend une matrice de premières fibres dans lesquelles sont réparties (a) des particules de charge et (b) des secondes fibres choisies parmi les fibres organiques synthétiques, caractérisé en ce que les particules (a) et les fibres(b) sont sous la forme d'une composition selon l'une quelconque des revendications 1 à 5.

23. Un matériau fibreux en feuille selon la revendication 22, caractérisé en ce que les particules de charge sont floculées.

24. Un matériau fibreux en feuille selon la revendication 22 ou 23, caractérisé en ce qu'il s'agit d'un papier, d'un carton ou d'un non-tissé déposé par voie humide.
